

Developer tools

Developer tools would include something such as testing webhooks, oauth flows, graphql explorers. These are tools setup specifically for developers to explore and test various API's publicly available.

- **Where are they hosted?** Do they host it themselves or is it hosted on AWS (usually it is. This is important because if it is hosted on AWS then your aim will be to read AWS keys).
- **What tools are available for developers?** Can I test a webhook event for example? Just **google for SSRF webhook and you'll see**.
- **Can I actually see the response on any tools?** If yes, focus on this as with the response we can prove impact easier if we find a bug.
- **Can I create my own application** and do the permissions work correctly? I had a bug where even if the user clicked "No" when allowing an application the token returned would still have access anyway. (The token should of not had permission to do anything!)

Take the example below on KREATIVE. The API docs mention the following below:
